Finite mixture estimation problem

Multivariate observation $\mathbf{x} = (x_1, \dots, x_r) \in \mathbb{R}^r$ from the mixture

$$g(\mathbf{x}) = \sum_{j=1}^m \lambda_j \mathbf{f}_j(\mathbf{x})$$

Assume independence of x_1, \ldots, x_r conditional of the component from which **x** comes (Hall and Zhou 2003,...):

$$g(\mathbf{x}) = \sum_{j=1}^{m} \lambda_j \prod_{k=1}^{r} f_{jk}(x_k)$$

i.e. the dependence is induced by the mixture.

Motivations, examples and notation Review of EM algorithm-ology

Finite mixture estimation problem

Multivariate observation $\mathbf{x} = (x_1, \dots, x_r) \in \mathbb{R}^r$ from the mixture

$$g(\mathbf{x}) = \sum_{j=1}^m \lambda_j \mathbf{f}_j(\mathbf{x})$$

Assume independence of x_1, \ldots, x_r conditional of the component from which **x** comes (Hall and Zhou 2003,...):

$$g(\mathbf{x}) = \sum_{j=1}^{m} \lambda_j \prod_{k=1}^{r} f_{jk}(x_k)$$

i.e. the dependence is induced by the mixture.

Goal: Estimate $\theta = (\lambda, \mathbf{f})$ given an i.i.d. sample from g

Motivations, examples and notation Review of EM algorithm-ology

イロト 不同 トイヨト イヨト 二日

Nonparametric mixture model

In parametric case $\mathbf{f}_j(\cdot) \equiv f(\cdot; \phi_j) \in \mathcal{F}$, a *parametric family* indexed by a parameter $\phi \in \mathbb{R}^d$

The parameter of the mixture model is

$$\boldsymbol{\theta} = (\boldsymbol{\lambda}, \boldsymbol{\phi}) = (\lambda_1, \dots, \lambda_m, \phi_1, \dots, \phi_m)$$

Usual example: the univariate Gaussian mixture model, $f(x; \phi_j) = f\left(x; (\mu_j, \sigma_j^2)\right) =$ the pdf of $\mathcal{N}(\mu_j, \sigma_j^2)$.

Motivations, examples and notation Review of EM algorithm-ology

・ロト ・ 日 ト ・ 日 ト ・ 日 ト

San

Nonparametric mixture model

In parametric case $\mathbf{f}_j(\cdot) \equiv f(\cdot; \phi_j) \in \mathcal{F}$, a *parametric family* indexed by a parameter $\phi \in \mathbb{R}^d$

The parameter of the mixture model is

$$\boldsymbol{\theta} = (\boldsymbol{\lambda}, \boldsymbol{\phi}) = (\lambda_1, \dots, \lambda_m, \boldsymbol{\phi}_1, \dots, \boldsymbol{\phi}_m)$$

Usual example: the univariate Gaussian mixture model, $f(x; \phi_j) = f\left(x; (\mu_j, \sigma_j^2)\right) =$ the pdf of $\mathcal{N}(\mu_j, \sigma_j^2)$.

Motivations here:

Do not assume any parametric form for the f_{jk} 's (e.g., avoid assumptions on tails...)

Motivations, examples and notation Review of EM algorithm-ology

・ロト ・ 同ト ・ ヨト ・ ヨト

DQC

Notational convention

We have:

- *n* = # of individuals in the sample
- *m* = # of Mixture components
- *r* = # of **R**epeated measurements (coordinates)
- Throughout, we use the subscripts:

$$1 \leq i \leq n$$
, $1 \leq j \leq m$, $1 \leq k \leq r$

Motivations, examples and notation Review of EM algorithm-ology

- *r* = # of **R**epeated measurements (coordinates)
- Throughout, we use the subscripts:

$$1 \leq i \leq n$$
, $1 \leq j \leq m$, $1 \leq k \leq r$

The log-likelihood given data $\mathbf{x}_1, \ldots, \mathbf{x}_n$ is

$$L(\theta) = \sum_{i=1}^{n} \log \left(\sum_{j=1}^{m} \lambda_j \prod_{k=1}^{r} f_{jk}(x_{ik}) \right)$$

Motivations, examples and notation Review of EM algorithm-ology

Motivating example: Water-level data

Example from Thomas Lohaus and Brainerd (1993).

The task:

- n = 405 subjects are shown r = 8 vessels, pointing at 1, 2, 4, 5, 7, 8, 10 and 11 o'clock
- They draw the water surface for each
- Measure: (signed) angle formed by surface with horizontal

Vessel tilted to point at 1:00

Review of standard EM for mixtures

For MLE in finite mixtures, EM algorithms are standard.

- A "complete" observation (X, \mathbf{Z}) consists of:
 - The observed, "incomplete" data X
 - The "missing" vector Z, defined by

for
$$1 \le j \le m$$
, $Z_j = \begin{cases} 1 & \text{if } X \text{ comes from component } j \\ 0 & \text{otherwise} \end{cases}$

・ロト ・ 同ト ・ ヨト ・ ヨト

Review of standard EM for mixtures

For MLE in finite mixtures, EM algorithms are standard.

- A "complete" observation (X, \mathbf{Z}) consists of:
 - The observed, "incomplete" data X
 - The "missing" vector Z, defined by

for
$$1 \le j \le m$$
, $Z_j = \begin{cases} 1 & \text{if } X \text{ comes from component } j \\ 0 & \text{otherwise} \end{cases}$

What does this mean?

- In simulations: We generate **Z** first, then $X|\mathbf{Z}_j = 1 \sim f_j$
- In real data, **Z** is a latent variable whose interpretation depends on context.

Semiparametric univariate mixture & EM-like algorithm

Identifiability: g(x) uniquely determines all λ_j and f_j 's

- **Parametric case:** When $f_i(x) = f(x; \phi_i)$, generally OK
- Nonparametric case: Some restrictions on f_i are needed

Bordes Mottelet and Vandekerkhove (2006) and Hunter Wang and Hettmansperger (2007) both showed that: for *f* symmetric about the origin and $\lambda_1 \neq 1/2$,

$$g_{\theta}(x) = \sum_{j=1}^{2} \lambda_j f(x - \mu_j)$$

is identifiable for the parameter $\theta = (\lambda, \mu, f)$.

The blessing of dimensionality (!)

Recall the model in the multivariate case, r > 1:

$$g(\mathbf{x}) = \sum_{j=1}^{m} \lambda_j \prod_{k=1}^{r} f_{jk}(x_k)$$

N.B.: Assume conditional independence of x_1, \ldots, x_r

- Hall and Zhou (2003) show that when m = 2 and $r \ge 3$, the model is identifiable under mild restrictions on the $f_{ik}(\cdot)$
- Hall et al. (2005) ... from at least one point of view, the 'curse of dimensionality' works in reverse.

The notation gets even worse...

Suppose some of the *r* coordinates are *identically distributed*.

• Let the *r* coordinates be grouped into *B* blocks of iid coordinates.

Denote the block index of the *k*th coordinate by

$$b_k \in \{1, ..., B\}, k = 1, ..., r.$$

• The model becomes

$$g(\mathbf{x}) = \sum_{j=1}^{m} \lambda_j \prod_{k=1}^{r} f_{j\mathbf{b}_k}(x_k)$$

Model and algorithm Examples Adaptive bandwidths in the npEM algorithm

San

The notation gets even worse...

Suppose some of the *r* coordinates are *identically distributed*.

• Let the *r* coordinates be grouped into *B* blocks of iid coordinates.

Denote the block index of the *k*th coordinate by

$$b_k \in \{1, \ldots, B\}, \, k = 1, \ldots, r.$$

• The model becomes

$$g(\mathbf{x}) = \sum_{j=1}^{m} \lambda_j \prod_{k=1}^{r} f_{j\mathbf{b}_k}(\mathbf{x}_k)$$

• Special cases:

- b_k = k for each k: Fully general model, seen earlier (Hall et al. 2005; Qin and Leung 2006)
- b_k = 1 for each k: Conditionally i.i.d. assumption (Elmore et al. 2004)

$$\mathbf{x}_{ au(1)}^{\ell} \leq \mathbf{x}_{ au(2)}^{\ell} \leq \cdots \leq \mathbf{x}_{ au(nC_{\ell})}^{\ell}$$

Define the weighted α -quantile estimate:

$$Q_{j\ell,\alpha}^{t+1} = x_{\tau(i_{\alpha})}^{\ell}, \quad \text{where } i_{\alpha} = \min\left\{s: \sum_{u=1}^{s} Z_{\tau(u)j}^{t} \ge \alpha n C_{\ell} \lambda_{j}^{t+1}\right\}$$

Iterative and per component/block quantiles

Let \mathbf{x}^{ℓ} denote the nC_{ℓ} data in block ℓ , and $\tau(\cdot)$ be a permutation on $\{1, \ldots, nC_{\ell}\}$ such that

$$\mathbf{x}_{ au(1)}^{\ell} \leq \mathbf{x}_{ au(2)}^{\ell} \leq \cdots \leq \mathbf{x}_{ au(nC_{\ell})}^{\ell}$$

Define the weighted α -quantile estimate:

$$Q_{j\ell,\alpha}^{t+1} = x_{\tau(i_{\alpha})}^{\ell}, \quad \text{where } i_{\alpha} = \min\left\{s: \sum_{u=1}^{s} Z_{\tau(u)j}^{t} \ge \alpha n C_{\ell} \lambda_{j}^{t+1}\right\}$$

Set
$$IQR_{j\ell}^{t+1} = Q_{j\ell,0.75}^{t+1} - Q_{j\ell,0.25}^{t+1}$$

Iterative & adaptive bandwidth illustration

Multivariate example with m = 2, r = 5, B = 2 blocks

- Block $1 = (x_1, x_2, x_3)$, components $f_{11} = t(2, 0)$, $f_{21} = t(10, 4)$
- Block 2 = (x₄, x₅), components f₁₂ = U_[0,1], f₂₂ = Beta(1,5)

San

Pros and cons of the npEM algorithm

- **Pro:** Easily generalizes beyond m = 2, r = 3 (not the case for inversion methods)
- Pro: Much lower MISE for similar test problems.
- **Pro:** Computationally simple (in the mixtools package).
- **Pro:** No need to assume conditionally i.i.d., and no loss of information from categorizing data (as for for the cutpoint approach)
- Con: Not a true EM algorithm (no monotonicity property)
 → Nonlinear Smoothed Likelihood MM algorithms Levine, Hunter and Chauveau (2010, ...)

3 Further extensions

・ロット 御マ キョット キョン

Further extensions: Semiparametric models

Component or block density may differ only in location and/or scale parameters, e.g.

$$f_{j\ell}(\mathbf{x}) = \frac{1}{\sigma_{j\ell}} f_j\left(\frac{\mathbf{x} - \mu_{j\ell}}{\sigma_{j\ell}}\right)$$

or

$$f_{j\ell}(\mathbf{x}) = \frac{1}{\sigma_{j\ell}} \frac{f_{\ell}}{f_{\ell}} \left(\frac{\mathbf{x} - \mu_{j\ell}}{\sigma_{j\ell}} \right)$$

or

$$f_{j\ell}(\mathbf{x}) = \frac{1}{\sigma_{j\ell}} f\left(\frac{\mathbf{x} - \mu_{j\ell}}{\sigma_{j\ell}}\right)$$

where f_i 's, f_ℓ 's, or the single *f* remain fully unspecified

For all these situations special cases of the npEM algorithm can easily be designed (some are already in **mixtools**).

Further extensions: Stochastic npEM versions

In some setup, it may be useful to simulate the latent data from the posterior probabilities:

$$\hat{\mathbf{Z}}_{i}^{t} \sim \textit{Mult}\left(1 \; ; \; Z_{i1}^{t}, \ldots, Z_{im}^{t}\right), \quad i = 1, \ldots, n$$

Then the sequence $(\theta^t)_{t>1}$ becomes a Markov Chain

- Historically, parametric Stochastic EM introduced by Celeux Diebolt (1985, 1986,...), see also MCMC sampling (Diebolt Robert 1994)
- In non-parametric framework: Stochastic npEM for reliability mixture models, Bordes Chauveau (COMPSTAT 2010...)
