1 Options on Zero Coupon Bond

Let r_t the dynamics for the instantaneous spot rate process. We note $B(t, T)$ the value of a unit-principal zero coupon bond at time t with maturity T . The price of a zero-coupon bond (ZCB) at time t for the maturity T is characterized by a unit amount of currency available at time T :

$$B(t, T) = E_Q \left(e^{-\int_t^T r(s)ds} \middle| F_t \right).$$

The price of a European call option with maturity T , strike K and written on a unit-principal zero-coupon bond with maturity $S > T$

$$ZBC(t, T, S, K) = E_Q \left(e^{-\int_t^T r(s)ds} (B(T, S) - K)_+ \middle| F_t \right).$$

The price of a European Put option with maturity T , strike K and written on a unit-principal zero-coupon bond with maturity $S > T$

$$ZBP(t, T, S, K) = E_Q \left(e^{-\int_t^T r(s)ds} (K - B(T, S))_+ \middle| F_t \right).$$

with Q risk-neutral measure. The put-call parity for bond options gives

$$ZBC(t, T, S, K) - ZBP(t, T, S, K) = P(T, S) - KP(t, T)$$

2 Cap and floor

We note $B(t, T)$ the value of a zero coupon bond at time t with maturity T . We note $L(t, T_i, \tau)$ the forward rate which set at time T_i the cash flow received at time $T_i + \tau$. Arbitrage leads to

$$1 + \tau L(t, T_i, \tau) = \frac{B(t, T_i)}{B(t, T_{i+1})} \quad (1)$$

spot libor rate is given by

$$1 + \tau L(T_i, T_i, \tau) = \frac{1}{B(T_i, T_{i+1})} \quad (2)$$

suppose that $t < T_M < T_{M+1}$ **Caplet and floorlet**

- we note $Cplt(t, T_M, K, \tau, N)$ the european caplet with maturity T_M , strike K on the spot libor rate $L(t, t, \tau)$ with nominal value N then at time $T_{M+1} = T_M + \tau$ the payoff is given by

$$N\tau(L(T_M, T_M, \tau) - K)_+$$

- we note $Fflt(t, T_M, K, \tau, N)$ the european floorlet with maturity T_M , strike K on the spot libor rate $L(t, t, \tau)$ with nominal value N then at time $T_{M+1} = T_M + \tau$ the payoff is given by

$$N\tau(K - L(T_M, T_M, \tau))_+$$

the cash flow at time $T_{M+1} = T_M + \tau$ is fixed at time T_M

Cap and floor suppose that $t = T_0 < T_1 < \dots < T_M$

- we note $Cap(t, T_s, T_M, K, \tau, N)$ the european cap with maturity T_M , strike K on the spot rate $L(t, t, \tau)$ then at times T_{s+1}, \dots, T_M the option leads the cash flows $N\tau(L(T_s, T_s, \tau) - K)_+, N\tau(L(T_{s+1}, T_{s+1}, \tau) - K)_+, \dots, N\tau(L(T_{M-1}, T_{M-1}, \tau) - K)_+$ ie

$$\text{at } T_i \text{ cash flow } N\tau(L(T_{i-1}, T_{i-1}, \tau) - K)_+$$

- we note $Floor(t, T_s, T_M, K, \tau, N)$ the european floor with maturity T_M , strike K on the spot libor rate $L(t, t, \tau)$ then at times T_{s+1}, \dots, T_M the option leads the cash flows $N\tau(K - L(T_s, T_s, \tau))_+, N\tau(K - L(T_{s+1}, T_{s+1}, \tau))_+, \dots, N\tau(K - L(T_{M-1}, T_{M-1}, \tau))_+$

at T_i cash flow $N\tau(K - L(T_{i-1}, T_{i-1}, \tau))_+$

1. a cap is a portfolio of caplets

$$Cap(t, T_s, T_M, K, \tau, N) = \sum_{i=s}^{M-1} Cplt(t, T_i, K, \tau, N)$$

2. a floor is a portfolio of floorlets

$$Floor(t, T_s, T_M, K, \tau, N) = \sum_{i=s}^{M-1} Fplt(t, T_i, K, \tau, N)$$

Is possible to derive explicit formulas for cap/floor prices under the analytically tractable short rate models given in Premia :

1. a cap is a portfolio of European Put options on zero-coupon bond

$$Cap(t, T_s, T_M, K, \tau, N) = \sum_{i=s}^{M-1} ZBP(t, T_i, K', \tau)$$

2. a floor is a portfolio of European Call options on zero-coupon

$$Floor(t, T_s, T_M, K, \tau, N) = \sum_{i=s}^{M-1} ZBC(t, T_i, K', \tau)$$

where

$$K' = \frac{1}{1 + K\tau}$$

3 Swaption

A swaption is an option on swap rate between time T_α and T_β which is given by :

$$S_{\alpha, \beta}(t) = \frac{B(t, T_\alpha) - B(t, T_\beta)}{\sum_{i=\alpha+1}^{\beta} \tau_i B(t, T_i)}$$

where $B(t, T_i)$ is the zero coupon bond price, and T_i ($i = \alpha, \dots, \beta$) the different maturities of the swap rate. A payer swaption is an option over a swap rate maturing at time T_α given by :

$$PSwpt_{\alpha, \beta}(t) = E_t \left[e^{-\int_t^{T_\alpha} r(s) ds} \sum_{i=\alpha+1}^{\beta} \tau_i B(T_\alpha, T_i) (S_{\alpha, \beta}(T_\alpha) - K)_+ \right].$$

A receiver swaption is an option over a swap rate given by :

$$RSwpt_{\alpha, \beta}(t) = E_t \left[e^{-\int_t^{T_\alpha} r(s) ds} \sum_{i=\alpha+1}^{\beta} \tau_i B(T_\alpha, T_i) (K - S_{\alpha, \beta}(T_\alpha))_+ \right].$$

A swaption can also be seen as an option of strick 1 over a certain coupon bearing:

$$RSwpt_{\alpha, \beta}(t) = E_t \left[e^{-\int_t^{T_\alpha} r(s) ds} (CB_{\alpha, \beta}(T_\alpha) - 1)_+ \right], \quad (3)$$

where

$$CB_{\alpha, \beta}(t) = \sum_{i=\alpha+1}^{\beta} c_i B(t, T_i)$$

whith $c_i = K\tau_i$ for $i = \alpha + 1, \dots, \beta - 1$ and $c_\beta = 1 + K\tau_\beta$.

Supposing now that there is an analitical formula for the zero coupon bonds of the form :

$$B(t, T) = A_1 e^{-A_2 r(t)},$$

then there exist an r^* such that analitical value of coupon bearing at time $t = T_\alpha$ with $r(T_\alpha) = r^*$ is 1:

$$\sum_{i=\alpha+1}^{\beta} c_i A_1(T_\alpha, T_i) e^{-A_2(T_\alpha, T_i) r^*} = 1$$

Replacing the strick 1 in (3) it appears that parenthesis is a sum : $(\sum)_+$ which is positive if and only if each term of the sum is positive. Thus :

$$\begin{aligned} RSwpt_{\alpha, \beta}(t) &= \sum_{i=\alpha+1}^{\beta} c_i E_t \left[e^{-\int_t^{T_\alpha} r(s) ds} (B(T_\alpha, T_i) - K_i)_+ \right] \\ &= \sum_{i=\alpha+1}^{\beta} c_i CALL(t, T_\alpha, T_i, K_i) \end{aligned}$$

Where $K_i = A_1(T_\alpha, T_i) e^{-A_2(T_\alpha, T_i) r^*}$ and $CALL(t, T_\alpha, T_i, K_i)$ is a call option at time t on a zero coupon bond $B(T_\alpha, T_i)$ maturing at time T_α with a strick K_i . Equally for a payer swaption :

$$PSwpt_{\alpha, \beta}(t) = \sum_{i=\alpha+1}^{\beta} c_i PUT(t, T_\alpha, T_i, K_i)$$

Where $K_i = A_1(T_\alpha, T_i)e^{-A_2(T_\alpha, T_i)r^*}$ and $PUT(t, T_\alpha, T_i, K_i)$ is a put option at time t on a zero coupon bond $B(T_\alpha, T_i)$ maturing at time T_α with a strike K_i .

Thus an analytical formula for call and put option leads to an analytical formula for a swaption.
